

# USACE Climate Change Update Part II

*Ecosystem Restoration Learning Exchange  
6 September 2011*

Kate White, PhD, PE  
Jeff Arnold, PhD  
Rolf Olsen, PhD

US Army Corps of Engineers  
**BUILDING STRONG**

# Recap: Summary Webinar Part I

- **Climate change adaptation is an active area for the USACE CW program because of lessons-learned from Hurricane Katrina and observed hydrologic and sea-level changes**
- **The climate change commitment requires both adaptation and mitigation**
- **Adaptation is challenging and has a longer time frame, but we are making progress**
  - **Pilots provide new knowledge**
  - **District-led guidance updates develop new knowledge**
- **More to come!**

# Planned Webinar Part II

- ~~Nationwide screening-level climate change assessment of the vulnerability of CW missions, operations, programs, and projects to climate change and variability~~
- Progress on climate guidance
- Integration of adaptation and mitigation
- Ecosystem considerations
- FY11 adaptation pilots (35 proposals!)

of Engineers**

**USACE CLIMATE CHANGE ADAPTATION POLICY STATEMENT**

As the Nation's largest and oldest manager of water resources, the US Army Corps of Engineers (USACE) has long been successfully adapting its policies, programs, projects, planning, and operations to impacts from important drivers of global change and variability. Climate change and variability, both observed and as projected for the future, are among those important drivers of global change having significant impacts to the management of US national water resources and infrastructure.<sup>1</sup> The Nation's water-resource infrastructure managed by USACE both protects public health and human life and annually provides billions of dollars of economic, social, and environmental benefits crucial to the continued progress of the Nation.

It is the policy of USACE to integrate climate change adaptation planning and actions into our Agency's missions, operations, programs, and projects. USACE shall continue undertaking its climate change adaptation planning, in consultation with internal and external experts and with our Districts, Divisions, and Centers, and shall implement the results of that planning using the best available – and actionable – climate science and climate change information. USACE shall also continue its efforts with other agencies to develop the science and engineering research on climate change information into the actionable basis for adapting its Civil Works and Military Programs missions to climate change impacts. Furthermore, USACE shall consider potential climate change impacts when undertaking long-term planning, setting priorities, and making decisions affecting its resources, programs, policies, and operations.

These actions which USACE is now conducting and has outlined for the future are fully compatible with the guiding principles and framework of the US Federal Interagency Climate Change Adaptation Task Force and the Implementing Instructions for Federal Agency Climate Change Adaptation issued on 4 March 2011 jointly by the Executive Office of the President's Council on Environmental Quality / Office of the Federal Environmental Executive (CEQ/OFEE) and the Office of Management and Budget.<sup>2</sup>

Together with CEQ, USACE recognizes the very significant differences between climate change adaptation and climate change mitigation in terms of physical complexity, fiscal and material resources, level of knowledge and technical readiness, and temporal and geographic scale. Because of these differences, understanding and implementing climate adaptation policies and measures requires very different knowledge, skills, and abilities than implementing mitigation measures. Relatedly, USACE understands and is acting to integrate climate adaptation (managing the unavoidable impacts) with mitigation (avoiding the manageable impacts). It is the policy of USACE that mitigation and adaptation investments and responses to climate change shall be considered together to avoid situations where near-term mitigation measures might be implemented that would be overcome by longer-term climate impacts requiring adaptation, or where a short-term mitigation action would preclude a longer-term adaptation action.

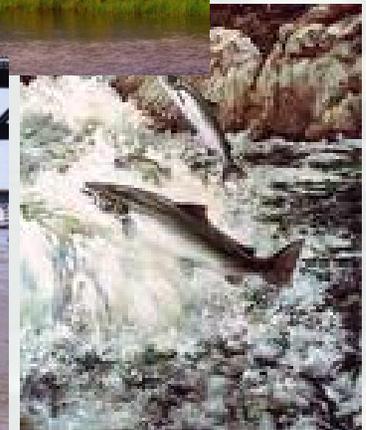

The successful implementation of this USACE adaptation policy will help enhance the resilience of the built and natural water-resource infrastructure USACE manages and reduce its potential vulnerabilities to the effects of climate change and variability. This success will allow USACE to continue fulfilling its missions using Integrated Water Resource Management to safeguard the Nation's tremendous investment in the built and natural water-resource infrastructure by mainstreaming climate change adaptation in all USACE activities.

## CLIMATE CHANGE

## Stationarity Is Dead: Whither Water Management?

P. C. D. Milly,<sup>1\*</sup> Julio Betancourt,<sup>2</sup> Malin Falkenmark,<sup>3</sup> Robert M. Hirsch,<sup>4</sup> Zbigniew W. Kundzewicz,<sup>5</sup> Dennis P. Lettenmaier,<sup>6</sup> Ronald J. Stouffer<sup>7</sup>

Systems for management of water throughout the developed world have been designed and operated under the assumption of stationarity. Stationarity—the idea that natural systems fluctuate within an unchanging envelope of variability—is a foundational concept that permeates training and practice in water-resource engineering. It implies that any variable (e.g., annual streamflow or annual flood peak) has a time-invariant (or 1-year-periodic) probability density function (pdf), whose properties can be estimated from the instrument record. Under stationarity, pdf estimation errors are acknowledged, but have been assumed to be reducible by additional observations, more efficient estimators, or regional or paleohydrologic data. The pdfs, in turn, are used to evaluate and manage risks to water supplies, waterworks, and floodplains; annual global investment in water infrastructure exceeds US\$500 billion (1).

The stationarity assumption has long been compromised by human disturbances in river basins. Flood risk, water supply, and water quality are affected by water infrastructure, channel modifications, drainage works, and land-cover and land-use change. Two other (sometimes indistinguishable) challenges to stationarity have been externally forced, natural climate changes and low-frequency, internal variability (e.g., the Atlantic multidecadal oscillation) enhanced by the slow dynamics of the oceans and ice sheets (2, 3). Planners have tools to adjust their analyses for known human disturbances within river basins, and justifiably or not, they generally have considered natural change and variability to be sufficiently small to allow stationarity-based design.

\*Author for correspondence. E-mail: cmilly@usgs.gov.

An uncertain future challenges water planners.

In view of the magnitude and ubiquity of the hydroclimatic change apparently now under way, however, we assert that stationarity is dead and should no longer serve as a central, default assumption in water-resource risk assessment and planning. Finding a suitable successor is crucial for human adaptation to changing climate.

*How did stationarity die?* Stationarity is dead because substantial anthropogenic change of Earth's climate is altering the means and extremes of precipitation, evapotranspiration, and rates of discharge of rivers (4, 5) (see figure, above). Warming augments atmospheric humidity and water transport. This increases precipitation, and possibly flood risk, where prevailing atmospheric water-vapor fluxes converge (6). Rising sea level induces gradually heightened risk of contamination of coastal freshwater supplies. Glacial meltwater temporarily enhances water availability, but glacier and snow-pack losses diminish natural seasonal and interannual storage (7).

Anthropogenic climate warming appears to be driving a poleward expansion of the subtropical dry zone (8), thereby reducing runoff in some regions. Together, circulatory and thermodynamic responses largely explain the picture of regional gainers and losers of sustainable freshwater availability

that has emerged from climate models (see figure, p. 574).

*Why now?* That anthropogenic climate change affects the water cycle (9) and water supply (10) is not a new finding. Nevertheless, sensible objections to discarding stationarity have been raised. For a time, hydroclimate had not demonstrably exited the envelope of natural variability and/or the effective range of optimally operated infrastructure (11, 12). Accounting for the substantial uncertainties of climatic parameters estimated from short records (13) effectively hedged against small climate changes. Additionally, climate projections were not considered credible (12, 14).

Recent developments have led us to the opinion that the time has come to move beyond the wait-and-see approach. Projections of runoff changes are bolstered by the recently demonstrated retrodictive skill of climate models. The global pattern of observed annual streamflow trends is unlikely to have arisen from unforced variability and is consistent with modeled response to climate forcing (15). Paleohydrologic studies suggest that small changes in mean climate might produce large changes in extremes (16), although attempts to detect a recent change in global flood frequency have been equivocal (17, 18). Projected changes in runoff during the multidecade lifetime of major water infrastructure projects begun now are large enough to push hydroclimate beyond the range of historical behaviors (19). Some regions have little infrastructure to buffer the impacts of change.

Stationarity cannot be revived. Even with aggressive mitigation, continued warming is very likely, given the residence time of atmospheric CO<sub>2</sub> and the thermal inertia of the Earth system (4, 20).

*A successor.* We need to find ways to identify nonstationary probabilistic models of relevant environmental variables and to use those models to optimize water systems. The challenge is daunting. Patterns of change are complex; uncertainties are large; and the knowledge base changes rapidly.

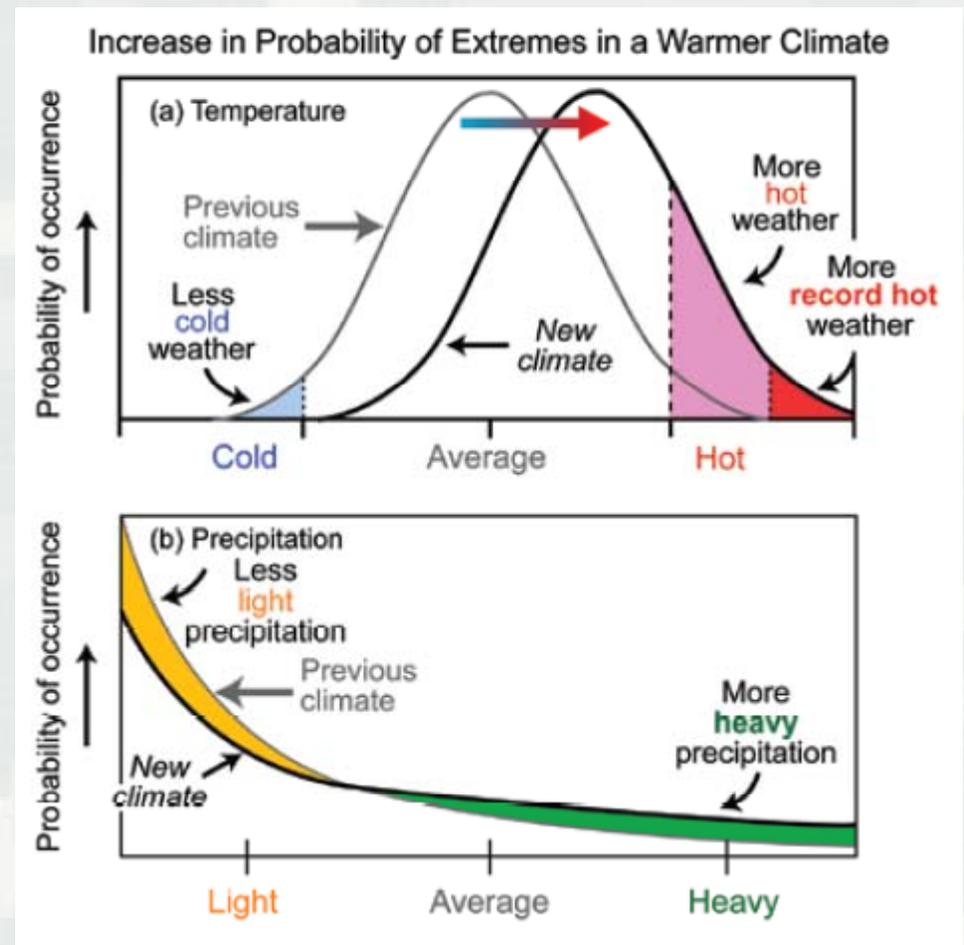

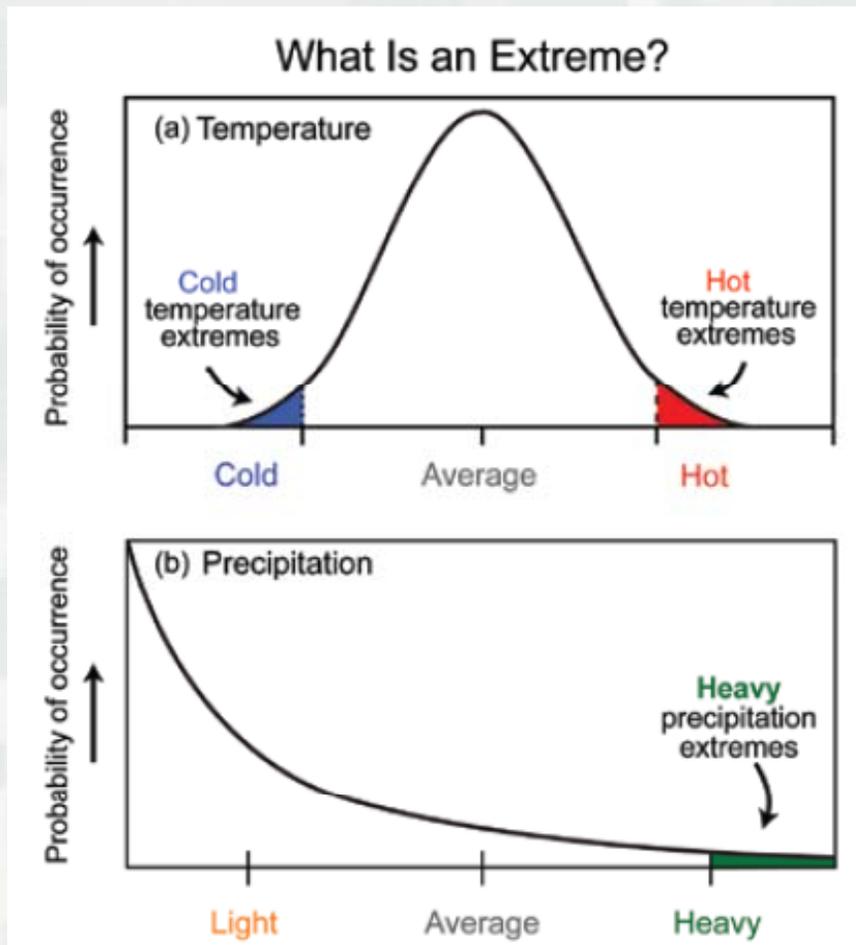

Under the rational planning framework advanced by the Harvard Water Program (21, 22), the assumption of stationarity was

**“Climate change undermines a basic assumption that historically has facilitated management of water supplies, demands, and risks.”**

**Stationarity allows us to assume that the statistical properties of hydrologic variables in future time periods will be similar to past time periods**

**Assessment of Potential for Producing Climate Change Information to Support Adaptation Decisions: A Climate Change and Water Working Group Initiative**

16 November 2011 Version 1.0

**Workshop Summary Report**

**Background and Motivation**

The Climate Change and Water Working Group (CCWWG), an informal inter-agency working group, was established in 2008 to coordinate and manage the water resources of the Department of the Interior (DOI). One of the primary goals of the CCWWG is to provide a forum for developing and coordinating water resources information for producing and communicating climate and climate change effects information for water resources management purposes.

One primary goal of the CCWWG is to provide the inter-agency Federal information to water-related resources and to identify their potential vulnerabilities to climate change effects. Federal agencies that manage water-related resources are planning the climate adaptation strategies and policies that will ensure a safe and efficient use of those resources to protect water from the risk of climate change. In doing so, they are also planning for the potential impacts of climate change on their water resources. The agencies have some questions about the information they need to make these decisions. More information that is available to them would help them make these decisions more effectively. The CCWWG is currently working on a project to develop a climate change effects information tool that will provide the information that is needed to make these decisions more effectively. This information tool will be developed in a way that will be consistent with the current state of the information that is available to the agencies. The CCWWG is currently working on a project to develop a climate change effects information tool that will provide the information that is needed to make these decisions more effectively. This information tool will be developed in a way that will be consistent with the current state of the information that is available to the agencies.

Assessing a Portfolio of Approaches for Producing Climate Change Information to Support Adaptation Decisions | A Climate Change and Water Working Group Workshop  
30-01 November 2010 | Boulder, CO  
Workshop Summary Report

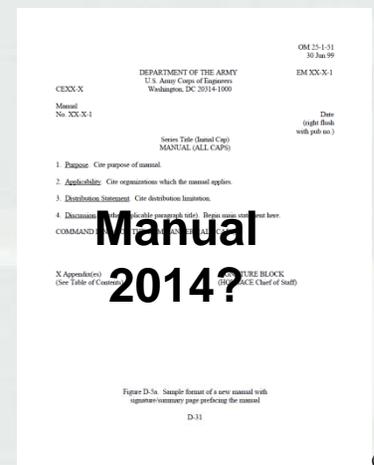

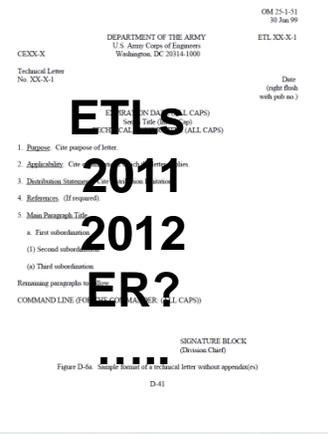

**Background and Motivation**  
The Climate Change and Water Working Group (CCAWWG), an informal scientist-to-scientist confederation across Federal agencies working with the science and operations and management of water resources in the US, sponsored a workshop in Boulder, CO, on 30-01 November 2010, to consider how to assess methods for producing and using climate science and climate change effects information for water resource-related adaptation decisions.

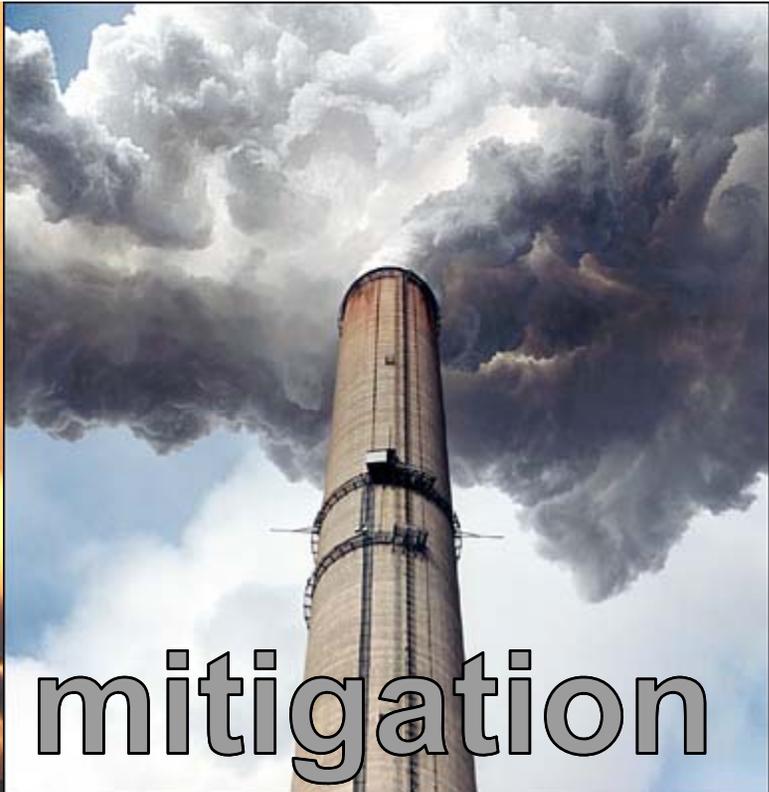

One common goal of the CCAWWG partners is to protect the enormous Federal investments in water-related resources by enhancing the resilience of water infrastructure and other water-related resources and by reducing their potential vulnerabilities to climate change effects. Federal agencies that manage water-related resources are planning the climate adaptation strategies and policies that will ensure effective and efficient use of those resources on temporal scales from the near (5-50 years) to long term (100-500 years or longer). Water resource planning decisions on such scales are the temporal ones, very widely, that are most relevant to the water resource management decisions that are made where decisions might be sensitive to climate change effects. Here, if it were available, having information on the temporal scales of climate change effects and on the uncertainties that might change the adaptation decisions that are made and on the uncertainties that might change the operation or management of investments where decision scales are broader. There, adaptation decisions can be general enough that an operating agency's decision process and outcomes would be insensitive to differences in predicted effects from uncertain climate projections.

Some CCAWWG partner agencies have begun sorting their initial climate adaptation questions by identifying the ones that are insensitive to differences in projected effects and the ones that might be sensitive to projection uncertainties. It may then be possible to recast some of the questions relative to projection uncertainties in a form that could use climate effects information with its current level of impression and uncertainty. Doing this, the CCAWWG partners recognize the important distinction made by Dettinger et al. (2008) that "adaptive responses to climate change [can be evaluated] without necessarily relying on accurate predictions as a key step in the assessment process." Climate change effects information need not be perfectly precise to enable agencies to take decisions and drive action on climate adaptation for water resources.

That is to say, to be useful – to be "actionable science" – for water resource management decisions, climate science and climate change effects information need not be free of projection uncertainties. Resource management agencies already take decisions and operate within complex networks of uncertain physical, hydrologic, and biological information. Uncertain climate change information can be integrated into many of those decision networks, but that information should begin with the scales of the various adaptation questions that confront the agencies. And for all scales of questions, climate effects information has high value only when that information can influence decisions and help drive action on adaptation strategies and policies.

<sup>1</sup> | CCAWWG Workshop on Approaches for Producing Climate Change Information

Climate change mitigation  
is about **CARBON**

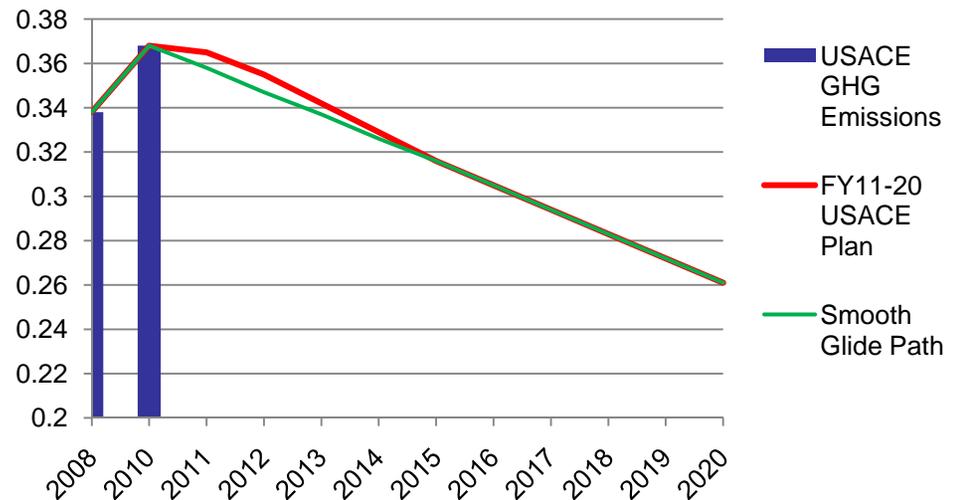

# Integrating Adaptation and Mitigation

- **Adaptation: Successfully perform our missions, operations, programs, and projects in an increasingly dynamic physical, socioeconomic, and political environment** 
- **Mitigation: Increase our water and energy efficiency while reducing GHG emissions** 
- **Investments must be integrated**
  - so that we don't implement near-term mitigation measures now that will be overcome by longer-term climate impacts requiring adaptation
  - Or that a short-term mitigation action forestalls a longer-term adaptation action

# USACE Mitigation

- Ops POC: John Coho
- ECoP POC: Antonia Giardina
- Primarily energy and water conservation and GHG emissions reduction
- USACE has set targets for GHG emissions reductions by 2020

# Sustainability

## small s

### (Mitigation, Conservation)

- *Avoiding the unmanageable*
- Conserving energy and water, decreasing GHG emissions
- Problem well understood, science available
- Many methods and technologies
- Inherently quantifiable (things)
- Results closely tied to implementation
  
- Relatively low cost

### Big S (Adaptation)

- *Managing the unavoidable*
- Ensuring robust and resilient mission and operations in an uncertain future
- Problem not well understood (“wicked problem”), little actionable science
- Methods and technologies in development
- Inherently qualitative (process)
- May have long time period between implementation and observable change; resulting changes may be difficult to ascribe to actions, requires collaborative approach that builds capacity and shares knowledge
  
- Low to high cost

# Adaptation

More Complex  
"Wicked"

## Dynamic

Cause and effect are far apart in space and time

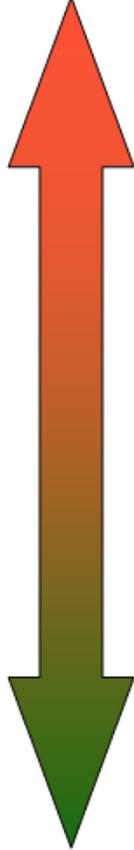

## Familiarity

Unfamiliar and unpredictable; relatively high uncertainty

## Social

Very different perspectives and priorities

solved using processes that are **"systemic, emergent and participatory."**

The degree to which the problem is spatially and temporally variable

The level of familiarity with, and predictability of, the future

The degree of common assumptions, values, rationales, and objectives among decision-makers

Less Complex

Cause and effect are close in space and time

Familiar and predictable; relatively low uncertainty

Common assumptions, values, rationales, and objectives

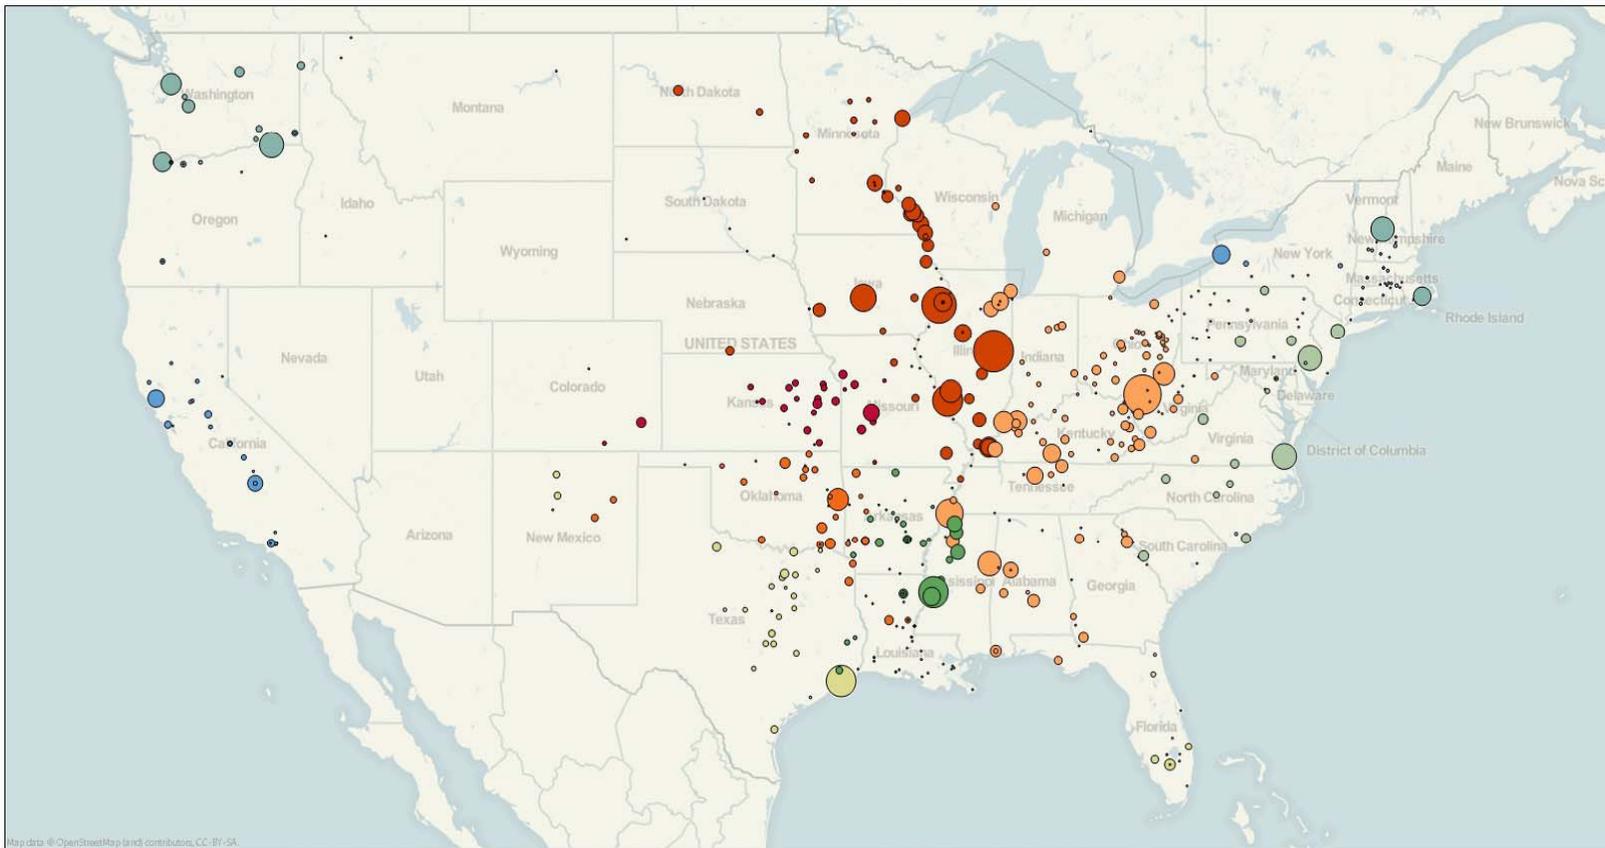

solved using processes that are **"piecemeal, backward looking, and authoritarian."**

# Mitigation

# Ecosystems and Climate Change

- **Examples from recent research:**
  - **Loarie et al 2009: The velocity of climate change**
  - **Jones et al 2009: Committed terrestrial ecosystem changes due to climate change**
  - **McDonald-Madden et al 2011: Optimal timing for managed relocation of species faced with climate change**
  - **Chen et al 2011: Rapid range shifts of species associated with high levels of climate warming**
- **Climate change encourages us to rethink our assumptions about ecosystems, how they function, and how they change over time**

- **Chen et al 2011 “found that observed latitudinal and elevational shifts (the latter more weakly) have been significantly greater in studies with higher levels of warming”**
- **Important factors were:**
  - **Time delay in species response (e.g., habitat specialists or immobile species)**
  - **Physiological constraints (e.g., sensitive to different physical variable at different life phases)**
  - **Alternate & interacting drivers of change, including nonclimatic factors**

**Fig. 1.** Relationship between observed and expected range shifts in response to climate change, for (A) latitude and (B) elevation. Points represent the mean responses ( $\pm$ SE) of species in a particular taxonomic group, in a given region. Positive values indicate shifts toward the pole and to higher elevations. Diagonals represent 1:1 lines, where expected and observed responses are equal. Open circles, birds; open triangles, mammals; solid circles, arthropods; solid inverted triangles, plants; solid square, herptiles; solid diamond, fish; solid triangle, mollusks.

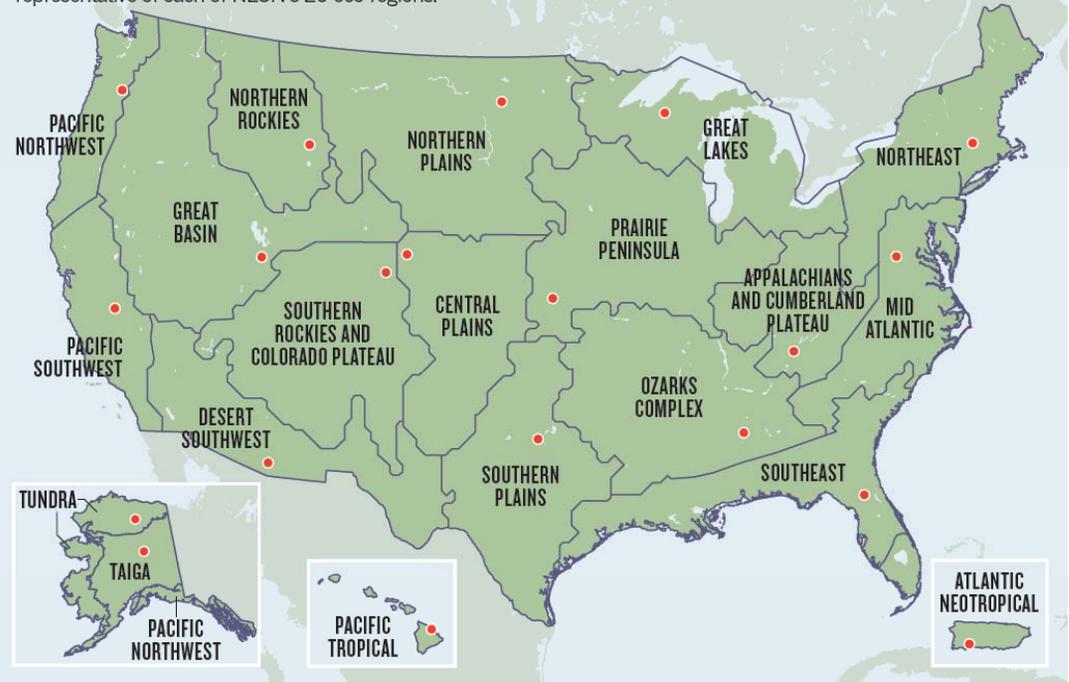

# National Ecological Observatory Network (NEON)

- 20 core observatories representing distinct eco-regions throughout the US
- Supplemented by temporary stations that can be relocated wherever data need to be collected
- Increase our understanding of national-scale changes

## GROUND COVER

Permanent research stations (red circles) are broadly representative of each of NEON's 20 eco-regions.
